

1. Binary Addition. Write pseudocode to add two  $n$ -bit binary numbers. Use two  $n$ -element arrays to represent each of the operands and an  $n+1$ -element array to store the results. **The least significant bit is stored in the last element of the array.** Analyze the runtime as demonstrated on INSERTION-SORT(A) in Chapter 2. For each line, define the number of times it is executed, and write the equation for the best and worst case runtime of the entire algorithm.

|    |                                     |       |   |
|----|-------------------------------------|-------|---|
| 1  | Binary-Add(A, B)                    |       |   |
| 2  | $n = A.length$                      | 1     | $T(n) = c_1 + c_2 + c_3 + c_4 + c_5n + c_6(n-1) + \dots + c_{15}(n-1) =$  |
| 3  | $carry = 0$                         | 1     | $c_5n + (c_6 + c_7 + \dots + c_{15})(n-1) + C$                            |
| 4  | $C = \text{new array, length } n+1$ | 1     | $C = c_1 + c_2 + c_3 + c_4$   |
| 5  | for $i = 0$ to $n-1$                | $n$   |   |
| 6  | $sum = A[i] + B[i] + carry$         | $n-1$ | Best Case (Only first if occurs):   |
| 7  | if $sum == 3$                       | $n-1$ | $T(n) = c_5n + (c_6 + c_7 + c_8 + c_9)(n-1) + C$                          |
| 8  | $carry = 1$                         | $n-1$ | Worst Case (Only Else occurs):  |
| 9  | $C[i] = 1$                          | $n-1$ | $T(n) = c_5n + (c_6 + c_7 + c_{10} + c_{13} + c_{14} + c_{15})(n-1) + C$  |
| 10 | else if $sum == 2$                  | $n-1$ |   |
| 11 | $carry = 1$                         | $n-1$ |   |
| 12 | $C[i] = 0$                          | $n-1$ |   |
| 13 | else                                | $n-1$ | The runtime of the loop doesn't get much better or worse. No              |
| 14 | $carry = 0$                         | $n-1$ | matter the size of $n$ (the length of $A$ and $B$ ) the loop will run $n$ |
| 15 | $C[i] = sum$                        | $n-1$ | times. There is some variation given the nature of the                    |
| 16 | $C[n] = carry$                      | 1     | conditionals.   |

2. Write pseudocode for a THETA( $n \lg n$ ) algorithm that, given a set  $S$  (i.e. unique numbers) of  $n$  integers and another integer  $x$ , determines whether or not there exist two numbers in  $S$  whose difference is exactly  $x$ . Briefly justify the runtime. Use a loop invariant to prove your algorithm is correct.

|    |                           |           |   |
|----|---------------------------|-----------|---|
| 8  | Set-Difference( $S, x$ )  |           |   |
| 9  | $n = S.length$            | 1         |   |
| 10 | $i = 1$                   | 1         | $n \lg n + cn + C$ . Merge-Sort has been proven to run in $\Theta(n \lg n)$ time, |
| 11 | $k = n-1$                 | 1         | and is the most expensive operation in this algorithm. Worst case, the            |
| 12 | Merge-Sort( $S, 0, n-1$ ) | $n \lg n$ | while-loop runs in $O(n)$ time.   |
| 13 | while $i < k$             | $n$       | $S[k] - S[i]$ gets closer to $x$ every iteration                                  |
| 14 | if $S[k] - S[i] == x$     | $n$       | LI: $S[0] \leq S[i] \leq S[k] \leq S[n-1]$ ,                                      |
| 15 | return true               |           |   |
| 16 | else if $S[k] - S[i] < x$ | $n$       | Base Case: $n=2$ , $(S[0]=S[i]) < (S[k]=S[1])$ ,                                  |
| 17 | $k = k - 1$               |           |   |
| 18 | else                      | $n$       | Termination: $i=k$ , $S[0] \leq S[i]=S[k] \leq S[n-1]$ or $S[k]-S[i]=x$           |
| 19 | $i = i + 1$               |           |   |
| 20 | return false              | 1         |   |

3. Use mathematical induction to show that when  $n$  is an exact power of 2, the solution of the following recurrence is  $T(n) = n \lg n$ . Don't forget to provide a base case.

$$T(n) = \begin{cases} 2 & \text{if } n = 2 \\ 2T(n/2) + n & \text{if } n = 2^k, \text{ for } k > 1 \end{cases}$$

Base Case:  $n=2^1$  ( $k=1$ ),  $T(2) = 2$

$$T(4) = 2T(2) + 4 = 8 = 4 * \log_2 4$$

$$T(8) = 2T(4) + 8 = 24 = 8 * \log_2 8$$

Guess:  $n \log n$

$$T(2^k) = 2T(2^{k-1}) + 2^k = n \log n$$

$$k=k+1 \rightarrow T(2^{k+1}) = 2T(2^k) + 2^{k+1}$$

$$= 2T(2^k) + 2^{k+1} = 2(2T(2^{k-1}) + 2^k) + 2^{k+1}$$

$$= 4T(2^{k-1}) + 2^{k+2} = n \log n$$

4. Let  $f(n)$  and  $g(n)$  be asymptotically positive functions. Prove or disprove each of the following conjectures. To disprove a statement, you need to provide only 1 counterexample.

- a.  $f(n) = O(g(n))$  implies  $g(n) = O(f(n))$ 
  - a. Counterexample:
  - b.  $f(n) = n$ ,  $g(n) = n^2$
  - c.  $f(n) = O(n^2)$
  - d.  $g(n) \neq O(n)$
  - e. Because  $f(n)$  is smaller than  $n^2$  (it can grow to  $n^2$  with  $O(f(n))$ ), but  $g(n)$  is already asymptotically larger than  $f(n)$
- b.  $f(n) = O(g(n))$  implies  $\lg(f(n)) = O(\lg(g(n)))$ , where  $\lg(g(n)) \geq 1$  and  $f(n) \geq 1$  for all sufficiently large  $n$
- c.  $f(n) = O((f(n))^2)$ 
  - a.  $f(n) = 1/n$
  - b.  $f(n)$  is asymptotically larger than  $f(n)^2$ .  $f(n)$  is an upper bound on  $f(n)^2$

## 5. Substitution Method

Using the master method in Section 4.5, you can show that the solution to the recurrence  $T(n) = 8T(n/4) + n$  is  $T(n) = \Theta(n^{\log_4 8})$ . Show that a substitution proof for establishing the upper bound with the assumption  $T(k) \leq ck^{\log_4 8}$  fails.

Then show how to subtract off a lower-order term to make a substitution proof work.

$$n^{\log_4 8} = n^{1.5}, O(n^{1.5}) = n^2, \text{ Guess: } n^2$$

$$T(n) \leq cn^2$$

$$T(n) \leq 8T(n/4) + n \leq 8c(n^2/16) + n \leq cn^2/2 + n \leq cn^2 + n \text{ which is not } \leq cn^2$$

We can subtract the lower order term  $n$  to fix this

$$\text{New Assumption: } T(n) \leq cn^2 - xn$$

$$T(n) \leq 8T(n/4) + n \leq 8(cn^2/16 - xn/4) + n \leq (cn^2/2 - 2xn + n) = cn^2/2 - n(2x+1) \leq cn^2 + n(1-2x)$$

When  $x = 1$ ,  $cn^2 - n$ , and  $cn^2 - n \leq cn^2 - xn$  which is our original assumption

## 6. Master Theorem

Use the Master Theorem to prove the bounds of the following. Justify your answer by defining  $f(n)$ ,  $a$ ,  $b$ , and a bound for epsilon, if appropriate. If using rule 3, show that the second condition also holds.

a.  $T(n) = 8T(n/3) + n^2$ .

a.  $a=8, b=3, f(n)=n^2$

b.  $\log_b a = \log_3 8 = \sim 1.89$

c.  $f(n) = n^2 = \Omega(n^c)$ ,  $((c = 2) > 1.89)$ , Case Three

d.  $8f(n/3) \leq kf(n)$

i.  $(8n^2)/9 \leq kn^2, k < 1$ , There exists a  $k$  that makes this true

e.  $T(n) = \Theta(f(n)) = \Theta(n^2)$

b.  $T(n) = 7T(n/3) + n \lg n$

a.  $a=7, b=3, f(n)=n \lg n$

b.  $\log_3 7 = \sim 1.77$

c.  $f(n) = O(n^c)$   $c < 1.77$ , case one

d.  $T(n) = \Theta(n^{\log_3 7})$

c.  $T(n) = 4T(n/2) + n^2$ .

a.  $a=4, b=2, f(n)=n^2$

b.  $\log_2 4 = 2$

c.  $f(n) = \Theta(n^{\log_2 4}) = \Theta(n^2)$ , case two

d.  $T(n) = \Theta(n^2 \lg n)$
